1. INTRODUCTION

This report describes an environmental imaging (EI) investigation carried out under contract to KAVIK-AXYS Inc. of Calgary, Alberta for EnCana Corporation of Calgary, Alberta. The survey was carried out on September 13th, 2006 at the Umiak N16 Sump, located southwest of Tuktoyaktuk, Northwest Territories (Figure 1).

The survey objectives were to investigate and delineate the extents of potential drilling wastes at the sump. This investigation was compared to two previous surveys, both directed by KAVIK-AXYS Inc. (see Essis Project #1442, August 2004 and #1560 02, September 2005), to determine possible changes in subsurface ion-distributions.

The Geonics EM38 and EM31 were used to map the lateral extents of ion-contaminated regions using electromagnetic (EM) inductive forces. Two Trimble Pathfinder Power DGPS receivers provided positional control. Data were differentially corrected using Inuvik, Northwest Territories base station data.

All project work was carried out in accordance to discussions with Mr. Chris Revak of KAVIK-AXYS Inc. of Calgary, Alberta.

Site Location

2. ENVIRONMENTAL IMAGING (EI) - DATA ACQUISITION

EI refers to the imaging of the subsurface for anomalous environmental conditions. Various tools are applicable to this process, each of unique capability and purpose. This section describes the tools used to image environmental subsurface conditions on site.

Appendix A contains geophysical (Geonics EM38 and EM31) and DGPS positioning (Trimble Pathfinder Power) specifications. Appendix B contains a technical paper by the instrument manufacturer (Geonics Limited). This paper provides in-depth technical background on the applied geophysical technique (Frequency-Domain EM induction).

2.1 LATERAL CONDUCTIVITY (GEONICS EM38/31)

Appendix A contains Geonics EM38/31 instrument specifications. The Geonics EM38/31 use electromagnetic (EM) inductive forces to delineate subsurface conductivities. These instruments are digitally synchronized to differentially-corrected GPS (DGPS). This arrangement allows positioning and geophysical data to be stored simultaneously on handheld dataloggers. Data are acquired swiftly at high sampling density. EM38 readings were taken in the 'EM38 – Horizontal Coils at Ground Level' mode, approximating measurements of the initial 1.5 m of topsoil (Table 1). EM31 readings were taken in the 'EM31 – Horizontal Coils at Hip Level' mode, approximating measurements of the initial 5 m of topsoil (Table 1).

Please note that an inherent property of EM signals prevents deep penetration into conductive media. Tabulated depths of penetration (Table 1) are skindepths of the penetrating EM signal and are a function, in part, of overall soil conductivity (conductive soil reduces depth-of-penetration). The various coil orientations are not used to delineate the depth-extent of contamination but rather the depth-onset of contamination.

TABLE 1
EM38/31 Coil Orientations and Corresponding Effective Depths of Penetration

<u>Coil Orientation</u>	<u>Effective Depth of Penetration</u>
EM38 – Horizontal Coils at Ground Level	1.5 m
EM38 – Vertical Coils at Ground Level	1 m
EM31 – Vertical Coils at Ground Level	2 m
EM31 – Horizontal Coils at Hip Level	5 m
EM31 – Horizontal Coils at Ground Level	6 m

2.2 DGPS POSITIONING (TRIMBLE PATHFINDER POWER)

Appendix A contains DGPS instrument specifications. Positioning data were differentially corrected using Inuvik, Northwest Territories base station data. The moving DGPS receiver (Rover) was synchronized to geophysical instruments providing positioning control of geophysical measurements. Although this system can readily apply corrections in real-time, post-processing using specialized software is more accurate and avoids potential interference by real-time correcting radio signals. Sub-meter positioning accuracies are generally possible. Table 2 lists various DGPS survey parameters. Site features have been surveyed on site and serve as reference markings for follow-up work.

TABLE 2
DGPS Survey Parameters

Base Station UTM Coordinate:	N7577533/E560870/51.22 m (HAE)
Rover UTM Zone:	08
Final UTM Datum:	NAD27 (NWT)

3. ENVIRONMENTAL IMAGING (EI) - DATA PROCESSING AND PRESENTATION

EI data processing was initiated infield and completed at headquarters. Data processing was designed to enhance results by carefully applying specific mathematical algorithms. Such algorithms may filter unwanted data, enhance trend continuity or highlight otherwise unclear or invisible data.

3.1 LATERAL CONDUCTIVITY (GEONICS EM38/31)

EM38/31 data were processed to moderate responses from buried metals and powerline interference. Additional data processing enhanced trend continuity and amplified hidden anomalies. Key data processing parameters are tabulated (Table 3) to enable future data processing repeatability. Two large-format ‘Lateral Conductivity Distribution (EM38/31) & Site Features’ maps were created (Maps 1/2 and 2/2) and are included in the clear plastic pouch accompanying this report. Reduced versions of both maps are bound into the report. The large-format maps detail site features better and offer finer EM-imaging than their smaller, bound counterparts.

The EM38 lateral conductivity image was overlain onto an aerial photograph taken by Essis crew during the mobilization flight. As the aerial photograph exhibits focal distortion, the DGPS surveyed features on the maps should be used for referencing field locations. The aerial photograph underlay is bound in following the report.

TABLE 3
EM38/31 - Key Data Processing Parameters

Data Gridding:	Kriging (1 x 1)
	Moving Average (5, 5)
Data Imaging:	Non-linear, 4 – 20 mS/m
Image Enhancement:	Resolution enhancement to 150 dpi, Low-Pass @ 3

3.2 DGPS POSITIONING (TRIMBLE PATHFINDER POWER)

Positioning data were corrected for ionospheric effects. Specialized processing software by Trimble Navigation incorporated Inuvik, Northwest Territories base station data to differentially correct all rover positions. PDOP (Positional Dilution of Precision) was consistently below 2.5. PDOP is a statistical measure of positional accuracy related to satellite geometry relative to the receiver. In general, PDOP values in excess of five suggest somewhat more inaccurate positioning. Map UTM coordinates were projected in NAD27 (NWT).

4. MAPS AND INTERPRETATION

Maps (1/2) and (2/2) are titled 'Lateral Conductivity Distribution (EM38/31) & Site Features'. The colour images on the maps represent the lateral conductivity distribution on site, also referred to as apparent conductivity. Apparent conductivity approximates the bulk conductivity from surface to skindepth of the primary EM field. Conductivity variations are generally caused by a combination of ionic contaminants (chlorides), natural soil salinity, buried metal (pipes, scrap, etc.), changes in soil type and saturation.

Metallic and ionic responses can often be distinguished by interpreting their characteristic behaviour. Such behaviour is a function of geometric coupling between the instrument and buried metal. Buried metal is easily identified when geometric coupling is maximized (for example, when surveying perpendicularly across pipelines). Consequently, buried metal is not always identified when coupling is minimized (for example, when surveying parallel to pipelines). Please note that while the EM38/31 respond to buried metal, these tools are not specifically designed to map buried metals.

The possibility of conductive media increases from dark blue (cold colours) to dark red (hot colours). Regions that have been surveyed (as revealed by the presence of geophysical

measurement stations, fine crosses) and are not coloured (but appear white) are also presumed background. Colour (blue) was omitted to ease the presentation of black site features.

Background readings can vary between sites in response to varying soil types. Dry accumulations of sand or gravel typically yield low backgrounds. Naturally occurring ions, fertilized, fine-grained and/or saturated soils yield elevated backgrounds. Elevated backgrounds can sometimes match magnitudes typical of contaminated regions. Lab results of test hole locations from within anomalous regions (hot colours) should reveal the cause of anomalous responses. Similarly, lab results of test hole locations from outside anomalous regions (cold colours) should reveal the nature of background responses.

The large-format maps are scaled at 1:600. The small-format, bound maps are scaled at 1:850. Data are presented in UTM coordinates and projected in NAD27 (NWT). The UTM grid coordinate system displays in units of metres (as opposed to degrees) and allows distance measurements to be read directly off the maps. UTM X and Y grid lines (the fine vertical and horizontal lines on the maps) are spaced 10 m apart. Site features have been DGPS surveyed and are included on the maps to provide reference control during follow-up work.

Aerial photograph #1 (bound in following the report) presents an overlay of the EM38 image to an aerial photograph of the site taken by Essis crew on September 13th, 2006 during a mobilization flight. As the aerial photograph exhibits focal distortion, the DGPS surveyed features on the UTM referenced maps should be used for finding field locations.

The first two surveys conducted on this site were performed in the falls of 2004 and 2005 (see Essis Project #1442 and #1560 02, respectively). Previous survey small-format maps are included in Appendix C. This current fall-2006 survey was conducted to identify potential changes in contaminant extents and magnitudes. To facilitate comparison of site conditions, presentation parameters, such as colour scale, were maintained from the initial surveys.

In general, EM38 Map (1/2) and EM31 Map (2/2) reveal shallower and deeper conductivity data on site, respectively. Conductivity response magnitudes ranging between 4 and 20 mS/m are considered very low and are typical of clean sands and silts commonly found in this region. The current survey exhibits slightly higher background conditions than in previous years. This may be explained by increased water saturation in the current year and/or warmer ground temperatures.

The sump location is identifiable in-field by a pile of fill material forming a 'topographic high', drafted central to the maps. The 'topographic high' is discernible on the aerial photograph as the rectangular shaped lighter ground pattern. The actual dimensions of the sump may exceed this visible boundary.

Deeper imaging EM31 (Map 2/2) reveals a subtle conductivity increase in the west half of the fill pile, suggesting potential drilling wastes are concentrated in this area. Shallower-imaging EM38 conductivities also appear relatively more elevated on the western side of the sump.

Both maps reveal elevated responses trending along the northern and southern perimeter of the fill pile. Greater EM38 response magnitudes suggest a predominantly shallow conductor in these areas. Generally wet conditions occurring around the sump, particularly on the north side as shown on the aerial photograph, may have influenced these slightly elevated shallow responses.

A potential contaminant migration path may appear as an elevated EM38 response trend extending south from the southeast corner of the sump. Based on response trends, the suspected flow path may run downslope from the sump and cross a natural ridge feature. Increased response magnitudes on the south side of the ridge suggest potential contaminant pooling. The ridge appears as a coarse-textured feature winding across the left side of the aerial underlay and has been outlined by a dashed line. EM31 data reveal a similar response trend with reduced amplitudes, suggesting potential contaminants are shallow.

However, EM38 surveying reveals two other conductivity hotspots of comparable magnitudes south of the ridge that do not appear related to elevated responses extending from the sump. These

occurrences suggest that the anomalous responses south of the ridge may be related to naturally conductive conditions, influenced by increased ion-concentrations and/or increased water saturation. Essis crew placed three lathe south of the ridge at the peak response targets to assist future reconnaissance. Other lathe were positioned at EM38 targets bordering the southeast and northwest sides of the sump.

Comparison of the current 2006-fall survey to the previous 2005 and 2004 surveys reveals that the EM31 instrument has reported progressively decreasing response amplitudes along the axis of the sump. Increased dispersion of elevated responses surrounding the sump was only apparent during the current survey. However, this trend may have also been attributable to increased background conductivities. EM38 data in and around the sump have been relatively patchy and discontinuous over the years.

EM38 trends and magnitudes along the suspected southern contaminant migration path and in the pooling area match those revealed by the 2005 survey. EM31 measurements were gathered in this area in 2006 only and cannot be compared with previous data.

Future soil coring should be strategically targeted to confirm suspected contaminated zones. Lab results from future borehole samples should be combined and correlated with geophysical data. The combined interpretation of all data ensures a comprehensive understanding of site conditions.

5. CONCLUSIONS AND RECOMMENDATIONS

The survey objectives were to investigate and delineate potential drilling wastes at the Umiak N16 Sump. This investigation was compared to two previous surveys directed by KAVIK-AXYS Inc. (see Essis Project #1442, August 2004 and #1560 02, September 2005) to determine possible changes in subsurface ion-distributions.

The Geonics EM38 and EM31 were used to map the lateral extents of ion-contaminated regions using electromagnetic (EM) inductive forces. Two Trimble Pathfinder Power DGPS receivers provided positional control. Data were differentially corrected using Inuvik, Northwest Territories base station data.

Geophysical findings from the current 2006 survey were compared to those from the previously conducted 2005 and 2004 surveys. A rectangular-shaped pile of fill material identified the general sump location. Lateral conductivity mapping revealed response magnitudes were reduced from the prior two years within the fill pile, where potential contaminants previously appeared clearly concentrated along its central axis. Elevated responses appeared more dispersed surrounding the sump in the current survey.

A potential ionic contaminant migration path extending south from the southeast corner of the sump pile had been initially identified in the previous surveys. Surveying along this path and the suspected contaminant pooling area at the end of the path, south of a ridge, revealed comparable response magnitudes and trends in the current survey.

However, the current survey was extended further west along the ridge and identified two separate conductivity hotspots exhibiting similar magnitudes as the suspected pooling zone. These elevated response targets did not appear related to the sump and may be due to natural influences. Lathe were positioned in-field at these and other targets to assist future site investigations.

Future soil sampling should be targeted to confirm the true nature of anomalous responses, with consideration given to target depth ranges. Lab results from future soil samples should be combined and correlated to all geophysical data. The combined interpretation of all data ensures a comprehensive understanding of site conditions.

Site features have been DGPS surveyed to assist follow-up work. As well, the aerial photographs taken of the site should support in-field feature identification. Caution is advised during subsequent sampling to avoid unidentified buried objects.
